OBSERVATION INFORMATION

Species	Date(s) Observed	Spawning	Rearing	Present	Anadromous
coho	4/13/00		X	1	<input checked="" type="checkbox"/>
cutthroat	4/13/00		X	4	<input type="checkbox"/>
Dolly Varden	4/13/00		X	3	<input type="checkbox"/>
					<input type="checkbox"/>
					<input type="checkbox"/>

IMPORTANT: Provide all supporting documentation that this water body is important for the spawning, rearing or migration of anadromous fish, including: number of fish and life stages observed; sampling methods, sampling duration and area sampled; copies of field notes; etc. Attach a copy of a map showing location of mouth and observed upper extent of each species, as well as other information such as: specific stream reaches observed as spawning or rearing habitat; locations, types, and heights of any barriers; etc.

Comments:

An electrofisher and minnow traps were used to determine the presence of coho salmon, cutthroat trout, and Dolly Varden char in "Muskeg Creek" on April 13, 2000. This stream is located in Mills Bay on the south side of Kasaan peninsula, originates in a muskeg system, is approximately 4 to 5 feet wide, and is made up of a series of pools and riffles with a gravel/cobble substrate. One coho juvenile was identified 50 feet upstream from saltwater. 4 cutthroat trout were trapped 1250 feet upstream from saltwater, and 3 Dolly Varden char were trapped 1300 feet upstream from saltwater. See attached map and field report by Moira Ingle, Area Habitat Biologist.

ACTION: Based on the presence of a coho juvenile and stream characteristics, **ADD MUSKEG CREEK FOR A DISTANCE OF 1000 FEET TO THE CATALOG OF WATERS IMPORTANT FOR THE SPAWNING, REARING AND MIGRATION OF ANADROMOUS FISHES FOR COHO REARING.**

SUBJECT: Fish Inspection Report
Mental Health Trust Sales
Mills Bay/Thorne Bay

On April 13, 2000, I conducted a fish habitat inspection with Greg Staunton (then representing Silva Engineering) at lands on the Kasaan Peninsula, near Thorne Bay, that are planned to be offered for timber harvest by the Mental Health Trust Land Office. After driving to Kasaan, we skiffed from Kasaan to Mills Bay, where we trapped and electro-shocked two streams to determine whether they are anadromous. The weather was sunny, with temperatures in the mid-50s. Both streams are located in Section 35 (T. 72 S., R. 85 E).

The first stream, "Muskeg Creek," is located in the center of the section, approximately $\frac{1}{4}$ down from the section line. The stream is approximately 4 to 5 feet wide at ordinary high water (OHW), and consisted of a series of pools and riffles with a gravel and cobble substrate and vegetatively controlled banks; gradient averaged less than 4% for the length of the stream. We shocked one two-year-old coho in a pool approximately 50 feet upstream from saltwater, and set a baited minnow trap a short distance upstream. We then proceeded upstream, where we set two more minnow traps, separated by about 200 feet, and continued shocking. After soaking for intervals of up to 2 hours, the traps contained a total of 4 cutthroat trout and 3 Dolly Varden char.

The stream originates in a muskeg system, approximately 1200 feet upstream, and is very narrow and choked with vegetation as it exits the muskeg area. No barriers (as defined in the Forest Practices Regulations Anadromous Fish Blockage table) were seen, but based on the characteristics of the stream channel, I called the upper extent of anadromous habitat at approximately 1000 feet from the mouth of the creek.

The second stream, "Mills Creek," is located at the head of Mills Bay. It is similar to the first stream, but slightly larger: approximately 6 to 7 feet wide at OHW, consisting of a series of pools and riffles, with vegetatively controlled banks. The substrate is gravel and cobble, and the gradient is less than 4%. At saltwater, I observed one unidentified salmonid fry. We shocked one two-year-old coho in a pool approximately 30 feet upstream from saltwater. As we moved upstream, I shocked a total of 2 cutthroat trout and 2 Dolly Varden char.

The stream splits into two branches about 1200 feet upstream. Upstream of the split, the gradient increased to approximately 6 percent on both branches, and stream width, number of pools, and water flow decreased markedly, with increasing quantities of skunk cabbage and other vegetation in the stream course. Although no barriers (as defined in the Forest Practices Regulations Anadromous Fish Blockage table) were seen, based on the characteristics of the stream channel, I called the upper extent of anadromous habitat at approximately 600 feet from the mouth of the creek.

We then skiffed back to Kasaan and I drove back to Craig. I plan to nominate these two streams for inclusion in the *Catalog of Waters Important for Spawning, Rearing and Migration of Anadromous Fishes*. Although only one coho was captured in each creek, I believe that fry of the year would be captured if the stream were trapped or shocked later in the year. Conditions for capturing fish were not ideal, because it was more than a month prior to emergence of fry, and the stream temperature was still fairly low (although I did not measure the temperature onsite, temperatures measured in other streams the following week were only 5 degrees C).

If you have any questions or need further information, please contact me.
